In prisms, He reflected rays has a whole of the energy Incident light wave so a brighter image is formed in prisms unlike in plane mirrors.

An

Any 2

(2)

- No need of Silvering is required in prisms

- Total reflecting prism can be used to

Invert an image, while a plane mirror can not.

- An object pin O is placed in front of convex mirror M₂ such that it forms a virtual diminished image I₁. The distance u of object O from convex is measured and recorded.

- A plane mirror M₁ is then placed between object O and the convex mirror such that it covers half aperture of the convex mirror.

- The plane mirror M₁ is adjusted until its own image I₂ of O coincides with image I₁ by no parallax method.

- Measure distances x & y. ✓

- focal length f of a concave mirror is got from $\frac{1}{u} + \frac{1}{v} = \frac{1}{f}$, where

u

$$u = x + y$$

$$v = -(x - y)$$

- It has a virtual eye ring. Any 2 02
- It is shorter than astronomical telescope when in normal adjustment.

(20)

3(a) Free oscillations are oscillations that take place in absence of dissipative forces such as air resistance and the amplitude of oscillation remains the same.

Damped oscillations are oscillations that take place in presence of dissipative forces and the amplitude of oscillation keeps on reducing with time due to loss energy to the surrounding.

B(i) Beats are periodic rise or fall in the intensity of sound heard when two notes of nearly the same frequency are played together.

(ii) A tuning fork of known frequency f_T is sounded together with a musical instrument of unknown frequency f .

The number of beats (n) per second are counted and beat frequency is noted as

$$f_b = \frac{n}{t}$$

One prong of a tuning fork is loaded with plasticine and sounded again together with the musical instrument and the new beat frequency f'_b is noted.

If $f'_b < f_b$ then frequency of the musical

When two notes are perfectly in tune, beats stop and the interference becomes purely constructive.

c(ii) Doppler effect is the apparent change in the frequency of waves heard due to relative motion between the observer and source of signals.

(iii)

$$f_a = \left(\frac{V - u_o}{V - u_s} \right) F$$

$$f_a = \left(\frac{340 - 20}{340 - 30} \right) \times 400 \quad \textcircled{03}$$

$$f_a = \underline{\underline{412.9 \text{ Hz}}} \quad \checkmark$$

d(i) Closed pipes give only odd harmonics while open pipes give both odd and even harmonics/tones. The more overtones the better the quality of sound thus open.

(iii) $f_n = \frac{nV}{4l} \quad n = 1, 3, 5, 7, 9, \dots$

$$860 = \frac{n \times 340}{4 \times 0.29}$$

$$n = 2.9 \approx 3 \quad \checkmark$$

The mode of vibration is the 3rd harmonic

Using

$$f_n = \frac{nV}{4(l+c)} \quad \checkmark$$

$$c = \left(\frac{3 \times 340}{4 \times 860} \right) - 0.29 \quad \textcircled{03}$$

$$c = 0.2965 - 0.29$$

$$c = 0.0065 \text{ m} \quad \checkmark$$

$$\underline{\underline{T = 20}}$$

If the path difference differ by a half number of wave-lengths, ~~destructive interference~~ occurs.

For maximum brightness $n\lambda = d \sin \theta$

minimum brightness $(n + \frac{1}{2})\lambda = d \sin \theta$

(05)

Where λ is Wavelength and d is the distance of separation between the two slits.

(c) (i) Equally spaced bright and dark fringes are observed and these fringes are parallel to the thin end of the wedge. (02)

(ii) The line of contact will still be a dark fringe but wavelength of light in water is less than in air hence the fringe separation (02) is reduced.

$$(d) \lambda = 5.8 \times 10^{-7} \text{ m}$$

$n = 2$ (second order)

$$\theta = 27^\circ$$

Using $d \sin \theta = n\lambda$

$$d = \frac{n\lambda}{\sin \theta}$$

$$= \frac{2 \times 5.8 \times 10^{-7}}{\sin 27^\circ}$$

$$\frac{1}{d} = \frac{1}{n\lambda \sin \theta}$$

$$\left(\frac{1}{d}\right) = \frac{\sin \theta}{n\lambda}$$

$$\left(\frac{1}{d}\right) \text{ No of lines per metre} = \frac{\sin 27^\circ}{2 \times 5.8 \times 10^{-7}}$$

$$= 3.91 \times 10^3 \text{ lines/m}$$

(04)

$$T = 20$$

4(a)(i) Interference is the overlapping of waves from different two coherent sources resulting into alternate regions of maximum and minimum intensity.

(ii)-Coherent sources must be close to each other

- Wave trains must have nearly equal amplitudes
- Wave sources must be coherent or have constant phase relationship.
- The screen must be as far as possible from the source.

(iii)

The surface to be tested is placed in contact with an optical flat surface to form an air wedge as shown below.

- Monochromatic light is made incident almost normally onto the upper glass slide.

It's partly reflected back at X and partly transmitted in the air film and reflected at Y.

The interference patterns produced by the reflected light from the air wedge is observed.

If the surface is flat, straight parallel and equally spaced bands will be observed and for if not flat, uneven bands will be seen.

(B).

- Consider two coherent sources of waves s_1 and s_2 at a distance of separation d , and the two waves meet at P.

- The path difference of the two waves s_1 and s_2 is $d \sin \theta \neq l_2 - l_1$.

- If the path difference is an integral multiple of wave lengths i.e. $(n\lambda)$ then

SEC C

5(a) Tesla is the magnetic flux density experienced by a current carrying conductor of length 1m carrying a current I of 1A placed at right angles to uniform magnetic field.

(b). (i) When a conductor is placed at right angles in magnetic field B and current I is passed through it transversely

The electrons in the conductor experience a force on side P and drift to side Q according to Fleming's left hand Rule.

This makes side Q to gain a negative charge and side P gains a positive charge hence causing an electric field intensity between P and Q until a maximum p.d is created.

This p.d is called hall voltage and it accounts for the occurrence of p.d between P and Q .

(ii) Electrons experience an electric force F_E due to electric field;

$$\text{At equilibrium } F_E = F_B \quad \checkmark$$

$$F_E = BeVs \sin\theta \quad \checkmark$$

$$E = BV \quad \text{but } \sin\theta = 90^\circ$$

But $v_H = E/d$ and v is velocity of

substitute eqn ② in ① electrons

$$E = B \left(\frac{I}{neA} \right) \quad \checkmark \quad \left(\frac{v_H}{d} \right) = BV \quad \text{and } d = a.$$

$$E = \frac{BI}{neA} \quad \checkmark \quad v_H = BNA \quad \text{and } I = neAt$$

$$v = \frac{I}{neA}$$

Where A - cross sectional area A . $\frac{03}{neA}$ but $A = a \times t$

$$v_H = \frac{BI \times a}{ne \cdot a \cdot t}$$

$$v_H = \frac{BI}{net}$$

Where t - thickness of conductor

When a coil is in the vertical position, a mechanical force is applied to move the coil in an anti-clockwise direction.

Side ab moves downwards and cd upwards.

As the coil rotates, the flux linking it changes, emf is induced causing a current to flow according to the direction determined by Fleming's Left Hand Rule. After the next vertical position ab & cd moves up and down respectively and this reverses the direction of current induced.

The output does not change in direction. It is because after the vertical position, the commutators change contacts from one carbon brush to another hence maintaining the direction of current at the output ie

(iii) When the coil rotates in a magnetic field, there is a change in flux and an emf is induced. But the direction of the induced current acts in such a way to oppose the emf generated and this is referred to as back emf.

$$(d) f = 2000 \text{ rev min}^{-1} = \left(\frac{2000}{60} \right) \text{ Hz} = 33.3 \text{ Hz}$$

$$B = 0.8 \text{ T}, N = 120 \text{ turns}, S = 10 \text{ cm}^2$$

$$E = BAN\omega \cos \theta$$

$$E = 0.8 \times (0.1)^2 \times 120 \times 12\pi \times \frac{2000}{60} \times \cos 30^\circ$$

$$E = 174.12 \text{ V}$$

6(a) Faraday's law states that the rate of change of magnetic flux is proportional to emf induced in the conductor. ①

Henz's law states that the induced emf acts in a conductor in such a way so as to oppose the change causing it. ②

(b)(i) Consider a coil of area A being rotated at a frequency f in a uniform magnetic field of flux density B about an axis which is perpendicular to the field.

From $\frac{d\Phi}{dt} \propto E$ ✗

(04)

d = diameter of the rim.

(ii) Using a solenoid.

The metal disc is placed at the centre of the solenoid and attached to the circuit carrying current through the solenoid when switch K is closed.

The plane of the disc is made perpendicular to the magnetic field.

The disc is rotated by the driving shaft and the speed of rotation is adjusted by until the galvanometer gives no deflection.

The number of rotations / revolutions of the disc in a given time t is counted and frequency f is determined.

The resistance R is calculated from;

$$E = B \pi r^2 f \quad \text{but } E = IR \quad \text{and } B = \mu_0 n I$$

$$\Rightarrow R = \frac{B \pi r^2 f}{I}$$

$$R = \mu_0 n \pi r^2 f$$

where n is the number of turns per metre of the solenoid.

$$T = 20$$

Qn. 7(a) Root mean square value of a.c. is the steady value of current that dissipates ^{heat} in the resistor at the same rate as the alternating current.

(b) Consider a capacitor of capacitance C connected to alternating source of voltage $V = V_0 \sin \omega t$.

Instantaneous charge on the capacitor is given \therefore

$$Q = CV \quad \text{and}$$

$$\text{Instantaneous current } I = \frac{dQ}{dt} \quad \text{but } I = \frac{d}{dt} CV_0 \sin \omega t$$

$$I = C V_0 \omega \sin \omega t$$

$$I = C V_0 \omega \frac{d}{dt} (\sin \omega t)$$

$$I = C V_0 \omega \cos \omega t \quad \text{but } I = I_0 \cos \omega t.$$

$$I_0 \cos \omega t = C V_0 \omega \cos \omega t.$$

$$I_0 = C V_0 \omega \quad (\text{peak value of current})$$

$$\therefore I = C V_0 \omega \cos \omega t.$$

c(i) From capacitative reactance $X_C = \frac{1}{2\pi f C}$ to

direct current is too much (infinity) since the frequency of d.c. is zero while for a.c. current, frequency is not zero hence the opposition by capacitor is smaller than that of direct current hence a capacitor allows a.c. to flow but not d.c.

(OR) c(i)

> When a capacitor is connected to a d.c. source, it charges to a maximum value of p.d. and current stops flowing through the capacitor.

> When a capacitor is connected to a.c. source, it charges and discharges repeatedly.

The a.c current ~~current~~ to be measured is passed through terminals X and Y.

Iron rods A and B are magnetised in the same sense ~~+~~ and so they repel.

Rods A and B ~~repel~~ each other with the a force proportional to the square of the current I.

The moveable rod moves with the pointer connected to the hair spring to provide the restoring torque to balance the repulsive force.

The deflection θ is proportional to the average value of square of current I i.e.

$$\theta \propto I^2.$$

05

(d) (i)

$$\theta = \tan^{-1} \left[\left(\frac{V_L}{V_R} \right) \right] \neq \left(\frac{IX_L}{I_R} \right) = \frac{X_L}{R} \quad \text{but } X_L = \omega L \quad X_L = 160 \times 0.5$$

$$\theta = \tan^{-1} \left(\frac{\omega L}{R} \right)$$

$$\theta = \tan^{-1} \left(\frac{160 \times 0.5}{60} \right)$$

02

$$X_L = 80 \Omega$$

$$\theta = \underline{53.1^\circ}$$

(ii) Using $Z = \sqrt{X_L^2 + R^2}$

$$Z = \sqrt{80^2 + 60^2}$$

$$Z = \underline{100 \Omega}$$

but From $V_o = I_o R$

$$I_o = \frac{V_o}{Z} = \frac{200}{100}$$

03

$$I_o = \underline{\underline{2.0 A}}$$

(iii) $P = I_o V_o = 2.0 \times 200$ (02) 100 W

8(a) Temperature coefficient of resistance is the factual (01) change in resistance of a conductor at 0°C per degree celsius rise in temperature.

Resistivity is resistance ~~of~~ across opposite faces of a cubical conductor of length of 1m.

b(c) When a current is applied ~~to pass~~ across the conductor, conduction electrons gain Kinetic energy and they drift in a direction opposite the applied current. They collide with ~~X ions~~ and lose their Kinetic energy to them.

The ions vibrate with increased amplitude as a result of the temperature of the wire ~~rises~~ (02) due to multiple collisions.

Using a micrometer screw gauge, diameter of wire d , is measured and its cross sectional area A is determined from $A = \frac{\pi d^2}{4}$

Connect a length ~~of~~ l ~~off~~ the wire across the left hand gap and a standard resistance R_s in the right hand gap as shown above.

Close switch K and tap the jockey along AB until a suitable balance length l_1 is obtained when the galvanometer shows no deflection.

l_2 is also noted

Determine the resistance of the wire, R from

$$R_x = \frac{R_s l_1}{l_2}$$

(2)

Repeat the procedure for different values of x and tabulate your results in a suitable table.

| x | L_1 | L_2 | R_{x2} |
|-----|-------|-------|----------|
| — | — | — | — |

Plot a graph of R_{x2} against x and determine the slope s of the graph.

Determine the resistivity of the wire $\rho = sA$

$$\rho = \left(\frac{s\pi d^2}{4} \right) \checkmark \quad \text{where } s - \text{slope} \\ d - \text{diameter of wire.}$$

(d) If K_1 is closed and K_2 open.

At balance p.d across $AC = 1.2$.

$$30.2 \times K = 1.2$$

$$K = \frac{1.2}{30.2}$$

$$K = 0.0397 \text{ N cm}^{-1}$$

If K_1 is opened and K_2 closed .

At balance p.d across $AC = \text{p.d across } 2\Omega$.

$$K \times L = I_a R \checkmark$$

$$0.0397 \times 26.8 = I_a \times 2$$

$$\Rightarrow I_a = 0.532 \text{ A}$$

Error in ammeter reading

$$e = I_a - I_r$$

$$e = 0.532 - 4.0$$

$$e = 0.132 \text{ A}$$

$$\text{percentage error} = \left(\frac{e}{I_a} \times 100 \right) \% \checkmark$$

$$= \left(\frac{0.132}{0.532} \times 100 \right) \% = 24.8 \% \quad \boxed{T=20}$$

or

9(a) (i) When a positively charged body is brought near a neutral body, electrons in the neutral body gets re-distributed within the neutral body such that they are attracted towards the positively charged body since unlike charges attract each other ie.

(3)

(ii) At sharp points, there is high electric field intensity which ionizes air around the charged conductor at sharp points.

The ions of opposite charge are attracted to the sharp point to neutralize the charge there.

This leads to loss of charge by the conductor which is known as corona discharge.

(B).

A positively charged metal sphere M is lowered into a metal can without touching it which is connected to a G-L-E and the leaf diverges. M is withdrawn and the leaf of G-L-E collapses.

Again M is lowered into the metal can (without touching it) and the leaf diverges to the same extent as before.

M is allowed to touch the can and the divergence remains unchanged.

M is withdrawn and on testing, it's found to have no charge.

Since M remains with no charge and the leaf of G-L-E remains diverged, there must have been charge inside the can equal and opposite to the charge on M, and the charge on the can must be residing outside and it is equal to the charge which was originally on M.

(4)

(4)

(c) Consider $+1C$ charge, d metres away from $+Q$ moved from C to B through a small displacement Δx .

$$\text{Force on } +1C F = \frac{Q}{4\pi\epsilon_0 x^2} \times$$

Work done to move the charge through Δx against the field is;

$$\Delta W = -F\Delta x \times$$

Total work done to bring the charge from infinity to a point at a distance d from the charge is;

$$W = \int_{\infty}^d -F dx \times$$

$$= \int_{\infty}^d -\frac{Q}{4\pi\epsilon_0 x^2} dx \times$$

$$= -\frac{Q}{4\pi\epsilon_0} \left[-\frac{1}{x} \right]_{\infty}^d \times$$

$$= -\frac{Q}{4\pi\epsilon_0} \left(-\frac{1}{d} - -\frac{1}{\infty} \right) \times$$

$$W = \frac{Q}{4\pi\epsilon_0 d} \times$$

05

Hence $V = \frac{Q}{4\pi\epsilon_0 d}$ ✓

(d)

Using $V = \frac{Q}{4\pi\epsilon_0 r}$ ×

$$V_{Q_1} = \frac{6 \times 10^{-6} \times 9.0 \times 10^9}{0.05} = 1.08 \times 10^6 \text{ V}$$

$$V_{Q_2} = \frac{4 \times 10^{-6} \times 9.0 \times 10^9}{0.05} = 7.2 \times 10^5 \text{ V}$$

02 1/2

$$\text{potential at } C = V_{Q_1} + V_{Q_2}$$

$$= (1.08 \times 10^6 + 7.2 \times 10^5)$$

$$= 1.8 \times 10^6 \text{ V}$$

Work done, $W = QV$

$$= (-4 \times 10^{-6} \times 1.8 \times 10^6)$$

(05)

$= -7.2 \text{ J}$ (negative sign means that work is done by the charge to overcome forces of attraction or repulsion) or against electrostatic forces of attraction and repulsion.

T = 20

Qn. 10 (a) (i) Dielectric field strength is the maximum p-d a dielectric material/insulator can withstand without conducting. Is the maximum electric field intensity an insulator can withstand without conducting.

A dielectric constant is the ratio of capacitance of a capacitor when the insulating material (dielectric) is placed between its plates to the capacitance of the same capacitor with a vacuum between its plates (without a dielectric).

When a dielectric is placed between two parallel plates of a charged capacitor, its molecules get polarized and its surfaces adjacent to the plates develop charge opposite to that on the plate of the capacitor.

This results into development of electric field intensity E_D between the polarized molecules of the dielectric and electric field intensity E_p due to the plates of the capacitor.

The resultant electric field intensity, E_R between E_p and E_D is given by; $E_R = E_p - E_D$ (E_p reduces) ie ($E \propto V$)

Thus $E = \frac{V}{d}$ implying that p.d between the plates reduces and capacitance $C = \frac{Q}{V}$ hence capacitance increases.

(6)

10 B : (i)

$$\text{Where } C_1 = C_2 = C_3 = C_4 = 6 \mu\text{F}$$

(ii) Using $E = \frac{1}{2} CV^2$

$$\begin{aligned} \text{But } C_E &= C_1 + C_2 + C_3 + C_4 \\ &= 6 + 6 + 6 + 6 \\ &= 24 \mu\text{F} \end{aligned}$$

$$\text{Energy, } E = \frac{1}{2} \times 24 \times 10^{-6} \times 12 \times 12$$

$$E = (0.000144 \times 12) \text{ J} \quad \textcircled{03}$$

$$E = 0.0017 \text{ J} \text{ or } 1.7 \times 10^{-3} \text{ J}$$

10(c) Initially energy stored by the capacitor is given by $E = \frac{1}{2} CV^2$ but $V = \frac{\Phi}{C}$ and

$$E = \frac{1}{2} C \left(\frac{\Phi}{\epsilon_0 A/d} \right)^2 \quad C = \frac{\epsilon_0 A}{d} \quad (\text{initial capacitance})$$

$$E = \frac{1}{2} \frac{d \Phi^2}{\epsilon_0 A} \quad \text{--- (1)}$$

Therefore doubling the distance between the plates of the capacitor when disconnected from the source;

$$\text{distance} = 2d$$

$$E' = \frac{1}{2} \cdot \frac{(2d) \Phi^2}{\epsilon_0 A} = 2 \left(\frac{1}{2} \frac{d \Phi^2}{\epsilon_0 A} \right)$$

$$E' = 2E \quad (\text{from equation (1)})$$

Thus energy will be doubled if the separation between the plates is doubled after it's disconnected from the battery (source).

(d).

$$C_1 = \frac{\epsilon_0 A}{d}$$

$$\frac{\epsilon_0 \epsilon_r A}{d} = C_2.$$

Now C_1 and C_2 are in parallel connection.

The resultant capacitance $C = C_1 + C_2$.

$$C = \frac{C_1}{3} + \frac{2C_2}{3}$$

$$C = \frac{\epsilon_0 A}{3d} + \frac{2\epsilon_0 A \epsilon_r}{3d}$$

$$C = \left(\frac{\epsilon_0 A + 2\epsilon_0 A \epsilon_r}{3d} \right)$$

$$C = \epsilon_0 A \left(\frac{1 + 2\epsilon_r}{3d} \right) \text{ as required. } \textcircled{B}$$
