(2)

1. (a) (i) D-block element is one in which the d sub energy level is fully filled or partially filled while transition element is one in which the d sub energy level (02) is partially filled in one of its stable oxidation states.

(ii) Zinc is not considered as a transition element because ^{both} zinc atoms and zinc ions have fully filled 3d sub energy level (orbitals).

(b) (iii) Complex ion is either positively charged ion or negatively charged ion in which the central atom or ion is bonded to atoms in molecules with lone pairs of electrons through coordinate bonds.

(iii) ionic radius ↗
charge on the ion ↗
vacant d orbitals (orbitals)

3. (a) (ii) Base ionisation constant is the ratio of the product of the molar concentration of the ions produced by the weak base to the molar equilibrium concentration of unionised weak base at a given temperature.

(ii) Solubility product is the product of the molar concentration of the ions raised to appropriate powers of a sparingly soluble electrolyte in its saturated solution at a given temperature.

(iii) Common ion effect is the lowering of the solubility of a sparingly soluble electrolyte on addition of a more soluble compound with one ion common to both at a given temperature.

$$\text{R.F.m of } \text{NH}_3 = 14 + 1 \times 3 \\ = 17$$

$$[\text{NH}_3] = \frac{0.68}{17} = 0.04 \text{ M}$$

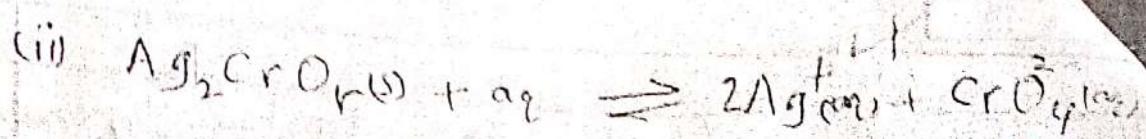

$$K_b = \frac{\alpha^2 c}{1-\alpha}$$

$$= \frac{(2.087)^2}{100} \times 0.04$$

$$= \frac{1 - 0.02087}{1.77936 \times 10^{-5}} \\ = 1.77936 \times 10^{-5} \text{ mol dm}^{-3}$$

$$= \frac{3.36 \times 0.63}{100} \\ = 0.0228489$$

$$[\text{Ag}_2\text{CrO}_4] = \frac{0.0228489}{332}$$

$$= 6.8819 \times 10^{-5} \text{ mol dm}^{-3}$$

$$[\text{Ag}^+] = 2 \times 6.8819 \times 10^{-5} \quad (32) \\ = 1.37639 \times 10^{-4} \text{ mol dm}^{-3}$$

$$K_{\text{sp}} = [\text{Ag}^+]^2 [\text{CrO}_4^{2-}]$$

$$= (1.37639 \text{ mol})^2 \times 6.8819 \times 10^{-5}$$

$$= 1.3037 \times 10^{-12} \text{ mol}^3 \text{ dm}^{-9}$$

(c) Excess of silver chromate is shaken with a given volume of distilled water until equilibrium is attained at a given temperature.
The mixture is filtered to obtain a filtrate which is a saturated solution of silver chromate at that temperature.

either

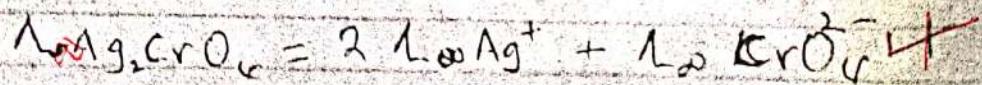

The electrolytic conductivity of the filtrate is measured using a conductivity cell.

The electrolytic conductivity of pure water is determined.

The electrolytic conductivity of the ions of silver chromate can be determined from the formula

$$K_{\text{soln}} = K_{\text{solution}} - K_{\text{water}}$$

The molar conductivity of the ions of silver chromate at infinite dilution can be obtained from tables in the data book and can be used to determine the molar conductivity of silver chromate from the formula

The molar concentration of the solution which is the solubility of the silver chromate can be determined from the formula

$$n_c = \frac{k}{c}$$

If the solubility of silver chromate is C mol/dm³, then the solubility product can be determined.

$$K_{\text{sp}} = [\text{Ag}^+]^2 [\text{CrO}_4^{2-}]$$

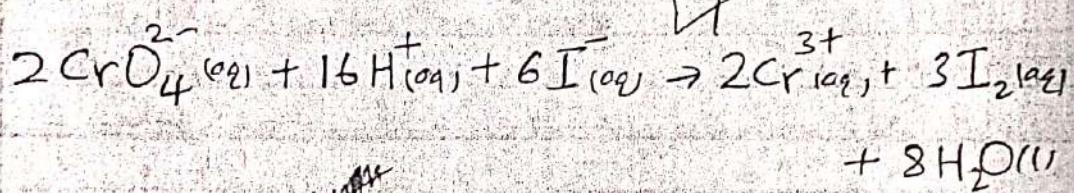

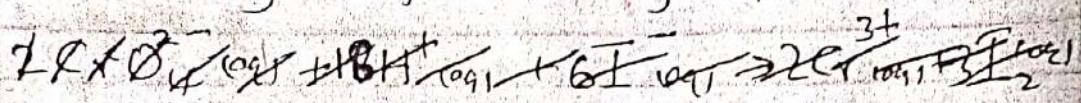

(11)

$$= (2c)^2 (c)$$

$$= 4c^3 \text{ mol/dm}^3.$$

On

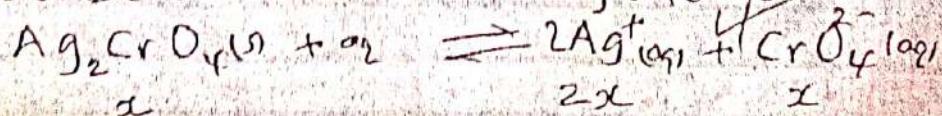

A known volume of the filtrate is pipetted, excess of potassium iodide solution and dilute sulphuric acid added. The reaction produces iodine according to following equation.

The iodine liberated is titrated against standard sodium thiosulphate using starch indicator.

The concentration of chromate ions is determined which is used to determine the concentration of silver chromate.

If $x \text{ mol/dm}^3$ is the molar concentration of silver chromate, the solubility can be determined as follows:

 x $2x$ x

$$K_{\text{sp}} = [\text{Ag}^+]^2 [\text{CrO}_4^{2-}]$$

$$= (2x)^2 (x) = 4x^3 \text{ mol/dm}^3.$$

(12)

Alternative
Topics & Ques

(i) In solubility of silver chromate ~~decreases~~[✓] because addition of silver nitrate increases the concentration of silver ions and excess silver ions will react with chromate ions to form insoluble silver chromate hence lowering the solubility.

(ii) Addition of ammonia solution increases the solubility of silver chromate because ammonia molecules react with silver ions to form a soluble complex called diamminesilver^(II) ion. The concentration of silver ions in the solution ~~reduces~~[✓] and thus more silver ions chromate dissolve to restore the equilibrium.

(e) When excess hydrogen chloride gas was bubbled through a mixture of salts (sea water), the solubility of sodium chloride ~~reduces~~[✓] due to the presence of chloride ions from hydrogen chloride and this will lead to precipitation of sodium chloride which can be filtered off, washed with little distilled water and then ~~dry~~ dried.

20

(13)

4. (a) Ideal solution is one with uniform intermolecular forces of attraction and there is no volume change and no enthalpy change on mixing the components.

(01)

(b)(i) Graph.

- (ii) The boiling point of pure butanol is 117°C while that of pure ethanol is 78.5°C .

Butanol has a higher relative formula mass than ethanol therefore the intermolecular forces in butanol are stronger than those of ethanol and thus more energy is required to break the intermolecular forces in butanol than those in ethanol.

(04)

When the amount of ethanol in the mixture is increased, the vapour will be richer in ethanol a more volatile component and the mixture boils at ~~on~~ a lower temperature because the vapour pressure of the mixture can easily reach external atmospheric pressure.

Therefore the ~~p~~ boiling points of ~~the~~ the mixture decrease towards the boiling point of pure ethanol.

(iii) When a liquid mixture containing 45% ethanol (55% butanol), i.e. it is heated, it will boil at ~~76°C~~^{70% ethanol} giving vapour of 70% ethanol which is a more volatile component.

When the vapour is condensed it will form a liquid mixture of the same composition as that of the vapour represented by X_1 .

When the condensed liquid is boiled, it will boil at a temperature of ~~87°C~~^{rich in ethanol} giving vapour of 88% ethanol which still a more volatile component which condenses to liquid of the same composition represented by X_2 .

Repeated ~~vapourisation~~ vapourisation and condensation produces ethanol as a pure distillate and the residue in the flask is pure butanol.

(04)

(c) (i) Raoult's law states that the partial vapour pressure of a volatile component in a liquid mixture at a given temperature is the product of the mole fraction and the vapour pressure of the pure component at that temperature.

(01)

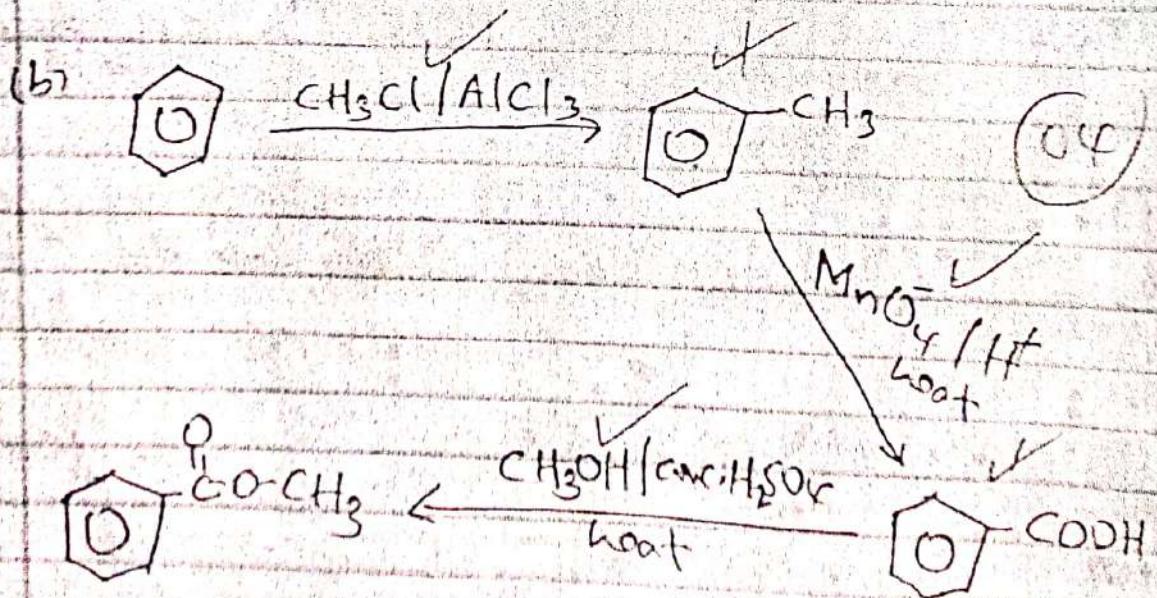

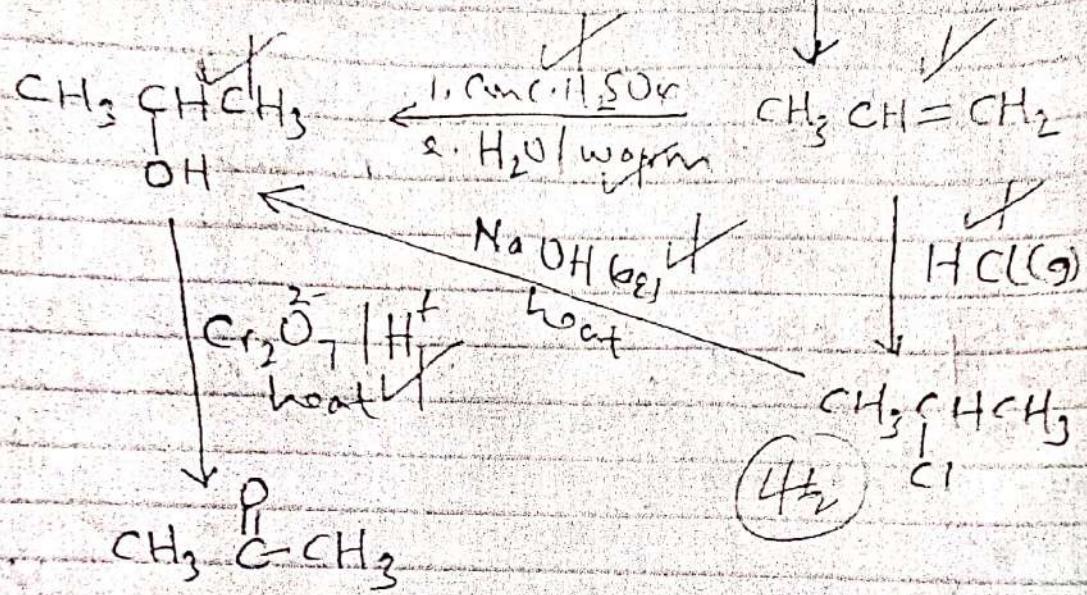

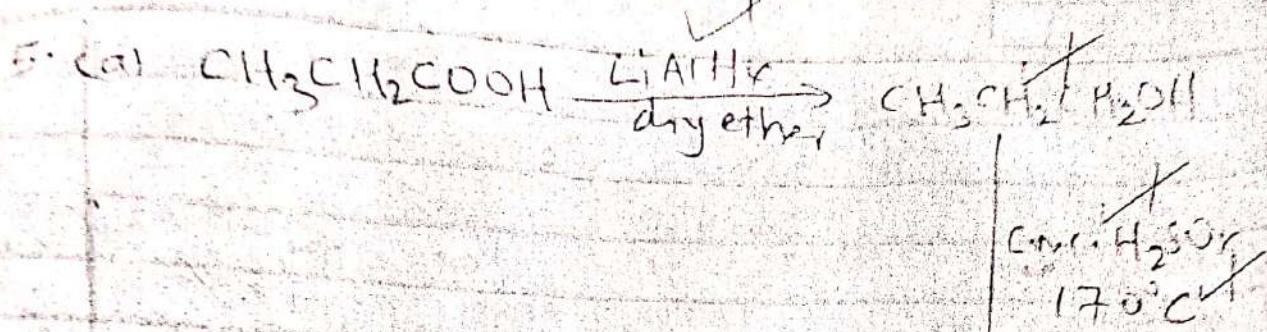

(ii) The intermolecular forces of attractions in pure components are different from those in the mixture and the vapour pressure above the mixture is either smaller or higher than that predicted by Raoult's law.

Raoult's law
 Partial vapour pressure of a volatile component in an ideal solution is proportional to mole fraction of the component.

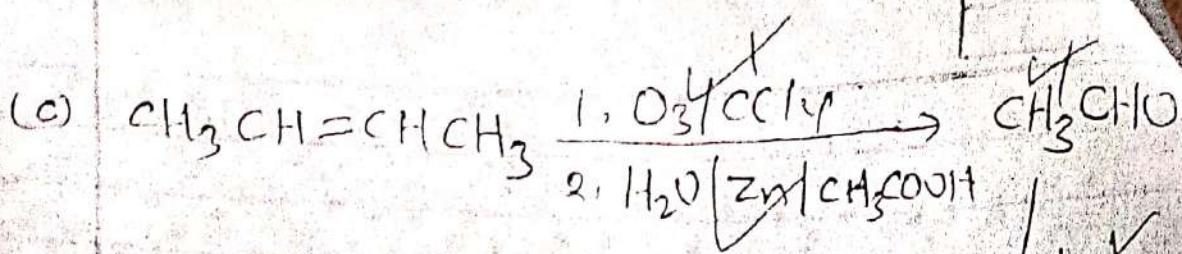

(16)

The mixtures that exhibit stronger intermolecular forces of attraction will have a lower vapour pressure and their boiling points will be higher than the pure components while those mixtures that exhibit weaker intermolecular forces of attraction will have a higher vapour pressure and their boiling points are lower than the individual components.

(6) (a) (i) Electrolytic conductivity is the conductance of a solution of an electrolyte placed between electrodes of cross sectional area A 1cm^2 or 1m^2 and a distance of 1cm or 1m apart.

(ii) Molar conductivity is the conductance of a solution containing one mole of an electrolyte placed between electrodes of unit cross sectional area and a unit distance apart.

(b) (i)

(02)

(02)

(22)

(c) For molar conductivity of Potassium chloride.

Initially the molar conductivity is low because the ions of Potassium chloride are closer to each other and this increases the ionic interference and thus reduces the ionic mobility.

As the dilution increases, the ions become far apart and thus the molar conductivity increases.

At infinity dilution, the ions move independently of each other and the molar conductivity remains constant.

For conductimetric titration of ethanoic acid, the conductivity initially is low because ethanoic acid is a weak electrolyte which partially ionises to form fewer hydrogen ions and ethanoate ions.

The initial drop in conductivity is due to removal of few highly conducting hydrogen ions and the conductivity then increases along BC due to the ions of the salt (in ammonium-ethanoate) which is being formed in the course of the titration.

Point C is the end point and the conductivity is due to the ions of the salt ^{only}. After the end point, the conductivity almost remains constant due to the suppression of the ionisation of excess ammonia by the ammonium ions from the salt.

 \end{aligned}$$

- (ii) The molar conductivity of lithium ion is ~~less~~ than that of sodium ion because lithium ion has a smaller ionic radius than sodium ion and thus lithium ion has higher charge density than sodium ion. The lithium ion strongly attracts water molecule and thus becomes heavily hydrated and thus its mobility reduces.

20

(27.)

Q. (iii) (a) Sodium, magnesium and aluminium form giant metallic structures with strong metallic bonds.
Sodium contributes one electron per atom towards metallic bond formation while magnesium contributes two electrons per atom towards metallic bond formation.
The metallic bonds in magnesium are much stronger than those in sodium and thus more energy is required to break the metallic bonds in magnesium than in sodium.
Aluminium also contributes two electrons per atom just like magnesium but the melting point of aluminium is slightly higher due to the difference in atomic radius. Aluminium has a smaller atomic radius than magnesium and the outermost electrons are strongly attracted to the nucleus making the metallic bonds in aluminium to be slightly stronger than those of magnesium.

(iii) Silicon has a giant covalent structure with a three dimensional net work of strong covalent bonds which require a lot of heat to break.
Chlorine is a diatomic molecule with very weak van der waals forces.

(23)

(iii) Phosphorus, sulphur and chlorine form simple molecular structures with weak van der waals forces. However, sulphur has slightly higher melting point than phosphorus because sulphur exists as S_8 molecules while phosphorus exists as P_4 molecules. (21)
 Sulphur has a much higher relative molecular mass than phosphorus and thus the van der waals forces in sulphur are stronger than those in phosphorus.

(b). Aluminium reacts with hot concentrated sodium hydroxide solution to form sodium aluminate and hydrogen gas.

$$2Al(s) + 2\bar{O}H(aq) + 6H_2O(l) \rightarrow 2Al(OH)_4^{(aq)} + 3H_2(g)$$

Silicon reacts with hot concentrated sodium hydroxide solution to form sodium silicate and hydrogen gas.

$$Si(s) + 2\bar{O}H(aq) + H_2O(l) \rightarrow SiO_3^{2-}(aq) + 2H_2(g)$$

Chlorine reacts with cold dilute sodium hydroxide solution to form sodium hypochlorite (sodium chlorate(1)), sodium chloride and water.

$$Cl_2(g) + 2\bar{O}H(aq) \rightarrow OCl(aq) + Cl(aq) + H_2O(l)$$

Chlorine reacts with hot concentrated sodium hydroxide solution to form
